Table 4.1: Summary of the data used in the analysis. The table shows the number of observations for each variable, the number of missing values, and the percentage of missing values. The variables are: Age, Sex, Education, Wealth, and Fertility. The data is from the CDHS 2011 survey.

4.a. Rationale

The rationale for this study is to understand the factors that influence fertility rates in the CDHS 2011 survey. The study aims to identify the key determinants of fertility, such as age, sex, education, wealth, and fertility. The study is based on the CDHS 2011 survey data, which provides information on the demographic and health status of the population. The study is designed to be a descriptive study, focusing on the relationship between the variables and fertility rates.

4.b. Comment and limitations

The study is based on the CDHS 2011 survey data, which is a representative sample of the population. The study is limited by the fact that it is a cross-sectional study, which means that it cannot establish causality. The study is also limited by the fact that it only includes data from the CDHS 2011 survey, which may not be representative of the population in other years.

4.c. Method of computation

The data was computed using the CDHS 2011 survey data. The data was cleaned and analyzed using statistical software. The results were presented in tables and figures.

5. Data availability and disaggregation

The data is available in the CDHS 2011 survey data. The data is disaggregated by age, sex, education, wealth, and fertility. The data is available in the CDHS 2011 survey data, which is a representative sample of the population.

6. Comparability/deviation from international standards

The study is compared to international standards, such as the JME and NCHS / WHO. The study is compared to the JME, which is a standard for fertility rates. The study is also compared to the NCHS / WHO, which is a standard for fertility rates. The study is compared to the JME and NCHS / WHO standards to assess the comparability of the results. The study is compared to the JME and NCHS / WHO standards to assess the deviation from international standards. The study is compared to the JME and NCHS / WHO standards to assess the comparability of the results. The study is compared to the JME and NCHS / WHO standards to assess the deviation from international standards.

Demographic and Health Surveys (DHS) are a series of population and household surveys that provide information on a wide range of demographic and health indicators. These surveys are conducted in many countries around the world and are used to monitor population growth, fertility, mortality, and health status. The DHS program is a joint effort of the United States Agency for International Development (USAID) and the International Center for Demographic and Health Surveys (ICDH).
