## 4.b. Comment and limitations

The data presented in this report are based on the results of the Demographic and Health Survey (DHS) conducted in 2018. The survey was designed to provide information on a wide range of demographic and health indicators. However, there are several limitations to the data that should be noted. First, the survey was a cross-sectional study, which means that it only provides a snapshot of the population at a single point in time. Second, the survey was conducted in a household-based format, which may not capture information on individuals who are not at home or who are institutionalized. Third, the survey used self-reported data, which may be subject to recall bias or social desirability bias. Finally, the survey did not collect data on certain indicators, such as HIV status, that are not routinely collected in household surveys.

## 4.c. Method of computation

The data were computed using the DHS software package, which includes a series of standard procedures for data management and analysis. The software package is designed to ensure the accuracy and consistency of the data across all DHS reports. The specific procedures used for the computation of the indicators in this report are described in the DHS Technical Report.

## 5. Data availability and disaggregation

The data presented in this report are available in the DHS database, which is a public database that provides access to the raw data from the survey. The database is available at the following URL: <https://dhsprogram.com/Data>. The data can be disaggregated by age, sex, and other demographic characteristics. However, the data are only available for the population aged 15 and over, and the disaggregation is limited to the variables included in the survey.

## 6. Comparability/deviation from international standards

The data presented in this report are compared to international standards to assess their comparability. The international standards used for comparison are the World Health Organization (WHO) standards for reproductive health indicators and the United Nations (UN) standards for demographic indicators. The comparison shows that the data are generally comparable to the international standards, with some deviations in certain indicators. For example, the fertility rate is slightly higher than the WHO standard, while the infant mortality rate is slightly lower than the UN standard. The deviations are likely due to differences in the survey methodology or the population characteristics. The DHS report provides a detailed analysis of the comparability and deviation from international standards for each indicator.
