## 4.b. Comment and limitations

The data presented in this report are based on the results of the Demographic and Health Survey (DHS) conducted in 2018. The survey was designed to collect information on a wide range of demographic and health indicators. However, there are several limitations to the data that should be noted. First, the survey was a cross-sectional study, which means that it only provides a snapshot of the population at a single point in time. Second, the survey was conducted in a household-based format, which may not capture information on individuals who are not at home or who are institutionalized. Third, the survey used self-reported data, which may be subject to recall bias or social desirability bias. Finally, the survey was conducted in a specific geographic area, which may not be representative of the entire population.

## 4.c. Method of computation

The data were computed using the DHS software package, which includes a series of standardized procedures for data management and analysis. The software package is designed to ensure the accuracy and consistency of the data across different surveys and countries. The data were then analyzed using a series of statistical tests to determine the significance of the results.

## 5. Data availability and disaggregation

The data are available in a disaggregated format, allowing for analysis by age, sex, and other demographic factors. The data are also available in a disaggregated format by region, allowing for analysis of regional differences. The data are also available in a disaggregated format by education level, allowing for analysis of the impact of education on health outcomes. The data are also available in a disaggregated format by wealth status, allowing for analysis of the impact of wealth on health outcomes.

## 6. Comparability/deviation from international standards

The data are compared to international standards to determine the extent to which the results are consistent with global trends. The international standards used for comparison are the World Health Organization (WHO) standards for reproductive health indicators and the United Nations Development Programme (UNDP) standards for social development indicators. The results of the comparison show that the data are generally consistent with international standards, although there are some deviations in certain areas. For example, the data show a higher rate of adolescent pregnancy than the WHO standard, and a lower rate of contraceptive use than the UNDP standard. These deviations may be due to a variety of factors, including differences in cultural norms, access to reproductive health services, and the quality of the data collection process.
