[Table 4.1: Summary of key findings from the 2011 CDHS. The table is organized into two main sections: 'Key findings' and 'Key findings (continued)'. The 'Key findings' section includes a table with 4 columns: 'Key finding', 'Description', 'Implication', and 'Recommendation'. The 'Key findings (continued)' section includes a table with 4 columns: 'Key finding', 'Description', 'Implication', and 'Recommendation'.

#### 4.a. Rationale

The rationale for the 2011 CDHS was to provide a comprehensive overview of the demographic and health status of the population. The survey was designed to collect data on a wide range of topics, including fertility, mortality, and health services. The data collected will be used to inform policy and program development, and to monitor progress towards the Millennium Development Goals.

#### 4.b. Comment and limitations

The CDHS 2011 was a large-scale survey that covered a wide range of topics. The data collected is comprehensive and provides a detailed picture of the population. However, there are some limitations to the data, including the fact that it is a cross-sectional survey and does not provide information on trends over time.

#### 4.c. Method of computation

The data for the 2011 CDHS was collected using a multi-stage sampling design. The first stage was the selection of the survey area, which was done using a probability-proportional-to-size method. The second stage was the selection of the households, which was done using a simple random sampling method.

### 5. Data availability and disaggregation

The data for the 2011 CDHS is available in a variety of formats, including hard copy and electronic. The data is disaggregated by sex, age, and education level. The data is also available in a disaggregated format by region and by district.

### 6. Comparability/deviation from international standards

The 2011 CDHS data is comparable to international standards. The survey was conducted using the same methodology as the 2005 CDHS, which was used to calculate the JME. The data is also comparable to the NCHS / WHO data. The Z score for the 2011 CDHS is 1.2, which is within the range of the international standards.

Demographic and Health Surveys (DHS) are a series of population and household surveys that provide information on a wide range of demographic and health indicators. These surveys are conducted in many countries around the world and are used to monitor population growth, fertility, mortality, and health status. The DHS program is a joint effort of the United States Agency for International Development (USAID) and the United Nations Population Fund (UNFPA). The surveys are conducted by national statistical agencies and are designed to be representative of the population. The data from the surveys are used to develop policies and programs to improve population health and development.
