## 4.b. Comment and limitations

The data presented in this report are based on the results of the Demographic and Health Survey (DHS) conducted in 2018. The survey was designed to provide information on a wide range of demographic and health indicators. However, there are several limitations to the data that should be noted. First, the survey was a cross-sectional study, which means that it only provides a snapshot of the population at a single point in time. Second, the survey was conducted in a household-based format, which may not capture information on individuals who are not at home or who are in institutional settings. Third, the survey used self-reported data, which may be subject to recall bias or social desirability bias. Finally, the survey did not collect data on certain indicators, such as mental health and certain types of violence.

## 4.c. Method of computation

The data were computed using the DHS software package, which is designed to calculate a wide range of demographic and health indicators. The software uses a complex set of algorithms to calculate these indicators, taking into account the unique characteristics of the survey data. The results of the computations are presented in the tables and figures in this report.

## 5. Data availability and disaggregation

The data presented in this report are available in both disaggregated and aggregated formats. The disaggregated data are available in the form of individual-level data, which can be used to analyze the relationship between individual-level factors and health outcomes. The aggregated data are available in the form of summary statistics, which can be used to compare the health status of different groups in the population. The data are available for all countries and regions included in the survey.

## 6. Comparability/deviation from international standards

The data presented in this report are compared to international standards to assess the comparability of the results. The international standards used for comparison are the World Health Organization (WHO) standards for demographic and health indicators. The results of the comparison are presented in the tables and figures in this report. The data are generally comparable to the international standards, but there are some deviations. For example, the prevalence of certain health conditions is higher than the international standards in some countries. This may be due to differences in the survey methodology or to differences in the health status of the population. The data are also compared to the results of other surveys conducted in the same country to assess the consistency of the results. The results are generally consistent with other surveys, but there are some differences. For example, the prevalence of certain health conditions is higher in the DHS than in other surveys in some countries. This may be due to differences in the survey methodology or to differences in the health status of the population.
