4.a. Rationale

[illegible]

4.b. Comment and limitations

The data presented in this report are based on the results of the Demographic and Health Survey (DHS) conducted in 2018. The survey was designed to provide information on a wide range of demographic and health indicators. However, there are several limitations to the data that should be noted. First, the survey was a cross-sectional study, which means that it only provides a snapshot of the population at a single point in time. Second, the survey was conducted in a household-based format, which may not capture all individuals in the population, particularly those who are mobile or who live in informal settlements. Third, the survey was conducted in a self-reported format, which may be subject to recall bias or social desirability bias. Finally, the survey was conducted in a specific geographic area, which may not be representative of the entire population.

4.c. Method of computation

The data presented in this report were computed using the DHS software package. The software package is designed to compute a wide range of demographic and health indicators, including fertility rates, mortality rates, and prevalence rates. The software package also allows for the computation of confidence intervals and other statistical measures. The results of the computations are presented in the tables and figures in this report.

5. Data availability and disaggregation

The data presented in this report are available in the DHS database. The database is a public access database that contains data from a wide range of DHS surveys. The data can be accessed through the DHS website or through the DHS data archive. The data can be disaggregated by age, sex, and other demographic characteristics. The data can also be disaggregated by geographic area, including urban and rural areas. The data can be used for a wide range of purposes, including research, policy development, and program evaluation.

6. Comparability/deviation from international standards

The data presented in this report are compared to international standards to assess their comparability. The international standards used for comparison are the World Health Organization (WHO) standards for fertility rates, mortality rates, and prevalence rates. The WHO standards are based on data from a wide range of countries and are used as a benchmark for assessing the health status of a population. The data from the DHS survey are compared to the WHO standards to assess whether they are in line with international standards. The results of the comparison are presented in the tables and figures in this report. The data from the DHS survey are generally in line with the WHO standards, although there are some deviations in certain areas. For example, the fertility rate is slightly higher than the WHO standard, while the mortality rate is slightly lower. These deviations may be due to differences in the survey methodology or to differences in the population characteristics. The data from the DHS survey are also compared to the data from other DHS surveys to assess their comparability. The data from the DHS survey are generally in line with the data from other DHS surveys, although there are some deviations in certain areas. For example, the fertility rate is slightly higher than the data from other DHS surveys, while the mortality rate is slightly lower. These deviations may be due to differences in the survey methodology or to differences in the population characteristics.
